

Canonical SIPS state transitions

State order is $[S, I, P]$ and $S + I + P = 1$; every flow transfers mass between compartments.

Aggregate pressure
 $\lambda(t) = \beta I(t)$
or degree mixing $\lambda_k = s_k k \sum_{\ell} M_{k\ell} \iota_{\ell} X_{\ell}$

Node-indexed pressure
 $\lambda_i = s_i \sum_j A_{ij} \iota_j I_j$
with node-specific $s_i, \iota_i, \dot{\gamma}_i, \omega_i$ and control bounds

The invariant is a modeling check, not an extra loss term in the ODE solver.
